ORACLE WEBLOGIC AND JREBEL
ENTERPRISE SCALE AT STARTUP SPEED
Why Companies Like Weblogic

At ZeroTurnaround, we get to see a LOT of different development environments. There are many debates on the merits and failures of various application servers, like ours from earlier this year: The Great Application Server Debate. One of the appservers that we see quite often is Oracle WebLogic Server (WLS). WebLogic has been around for quite a while, since 1997, and it boasts an impressive feature set. It’s scalable, it’s got solid and supported implementations of the Java EE JSRs and Enterprise OSGi, and it’s an industry standard, so it’s reusable information in future jobs. It also has a robust and functional administration console that helps configure complex systems easily.

From a production standpoint, WebLogic is a great choice and is the standard amongst most high availability (due to the clustering and domain architecture), high throughput industries where uptime and performance are the driving forces - such as finance, governments, healthcare, and Software As A Service providers, especially as the backbone of the Oracle Fusion Middleware suite and with specialized editions like Server Process Edition with Oracle BPM integration.
Why Devs Dislike Weblogic

While WebLogic is great for production, it leaves much to be desired on the development side due to its poor user experience. WLS is kind of slow for the normal developer use case, and Java EE applications can be large and unwieldy. Most of the features that make WebLogic so great for production environments often go unused or even misconfigured in development. Also, typically the type of critical applications that run on WLS are larger than average. Developers like to write software, not fight with their tools. When we meet WLS users, a daily occurrence, and ask them if they enjoy using WebLogic, we’re met with ambivalence. They tell us it’s the most capable application server, but it is really slow for them in their daily work.

Usually they’re willing to either go to great lengths to speed it up, or have trained themselves to work their application server redeployes into their schedule (the “2:30pm I’m redeploying coffee run”, for example).
Just how slow is it?

ZeroTurnaround has collected quite a bit of data from WebLogic users on their redeploy habits, such as:

- **how many times** per hour they redeploy their application
- **how long** each redeploy takes
- and what percentage of their precious **coding time is wasted** on redeloys.

We gather this information in a survey that is filled out by all of our prospective customers. The survey also asks several questions relating to frameworks and application servers used, and general coding habits of the individual and organization. Through this survey, we have been able to gain some insight into our customers as well as their tooling. From the survey, we have harvested some hard data regarding the redeployment habits and times of developers using WebLogic, from **version 9 through 12c**.
The average developer using WebLogic redeploy and interactively tests their application in their development environments **3.1 times per hour**.
The average build and deploy phase takes **7.46 minutes**, which tells us that approximately **23 minutes of every hour** are wasted waiting to interactively validate the results of the code change. Given an 8 hour workday, this means that about **39% of the day is wasted** on this redeploy phase. From our experience, this is most likely skewed given the dynamic level of coding activity through the duration of the sprint or life cycle of the project.

**3.1 per hour**
redeploy & tests

**7.46 minutes**
build & deploy

**23 minutes**
wasted per hour

**39% of day**
on redeploy
Most likely very little of the time is wasted in the beginning, since that time is spent planning out the project or tasks for the sprint. However as deadlines approach, more and more time is spent rapidly coding to achieve goals and meet deadlines. What that really translates to is more time spent working overtime as deadlines approach, unhappy and stressed developers, and potentially poorly written code.
Programmers are always looking for hacks to speed up their development environments and the systems they code against. In the last few years, the forced downtime of using WebLogic and a full Java EE stack during the redeploy phase has become the new target for optimization by developers and their organizations. There are several mitigation tactics. Some of them are ingenious and others are almost insane, and we have seen them all. One of the most common tactics is to use a different, faster, lighter-weight application server in development than production. This generally involves developers running Tomcat or Jetty on their development machines and just packaging the Oracle implementations of the Java EE specifications they’re coding against.

How do devs fix this now?
As far as strategies go, this is fairly reasonable, but invariably there is the merge phase where developers try to run their code against a real instance of WLS and experience hard-to-track-down bugs due to differences in implementations. At the other end of the spectrum, we see dev teams spend so much time trying to inline and pre-build resources and artifacts that they spend as much time working on their build systems as they do developing their products.

This practice, while well-meaning, leads to the build system becoming “black magic” and the more junior developers will have no idea how their application is actually built. Oracle knows that WebLogic is slow, they even provide an enhanced version of HotSwap called FastSwap with WebLogic to help mitigate the reduction in developer productivity, but it’s only covers a small number of code changes and doesn’t have any framework integration. The vast majority of developers on WebLogic just deal with their downtime and try to find creative things to do while they wait.
There is a way to keep using Java EE and keep using WebLogic, but completely eliminate the downtime from redeploys. JRebel is a productivity tool that allows developers to more interactively test their code without sitting through the hurry-up-and-wait rebuild/redeploy cycle for their applications and application servers. There are currently over 65,000 active users of JRebel, and many of our users use WebLogic. JRebel is as easy to install as a simple jar drop-in into your JVM’s arguments, or an IDE plugin if you’re using any of the mainstream IDEs like Eclipse, MyEclipse, Rational Application Developer (RAD), IntelliJ IDEA, or NetBeans. With JRebel enabled in your environment, you can keep your current tech stack and not resort to any of the compromises previously mentioned. Based on the numbers shown above, JRebel enables WebLogic users to be approximately 75% more productive.
module projects. JRebel also hotpatches frameworks and their configurations. Over 100 frameworks are currently supported including the most used portions of the Java EE spec: CDI, EJB, JPA, JSF, all of the JAX components, and more. JRebel also supports making changes to application servers running remotely. A common WebLogic scenario is to have a VM running WLS and a developer pushing code to the remote instance. JRebel eliminates that downtime as well, and can push the code delta to the remote WLS instance and hotpatch the code without any loss of productivity.

The current trend in application server development is moving toward faster and more lightweight application servers, often with smaller feature sets. However, even appserver developers acknowledge that no matter how fast the appserver itself is, the application initialization is out of their hands. Oracle is making incremental progress with newer versions of WebLogic; it is getting faster over time. However, if your application still takes 2 to 3 minutes to initialize, you are still wasting a significant portion of your day. JRebel uses bytecode instrumentation to allow unlimited class and resource reloading throughout your application, even in multi-
With JRebel, you can test your code while you’re writing it and make changes without losing context or focus. This results in vastly better code, as it allows for developers to make quick experiments, see the results, and revert back immediately if needed. For around $1 per day, you can make huge productivity gains, write better software, and enjoy doing it.

JRebel improves the user experience for the average WebLogic developer so much, that even Oracle is a customer, and many of their ADF and platform developers are happy JRebel users.

JRebel is available as a free 14 day trial from our website. Become a rockstar in your organization, and join the rebellion to fight redeploy!
